

Individual response to ionizing radiation: radiosensitivity, radiosusceptibility and radiodegeneration

Michel Bourguignon, MD, PhD

Professeur de Biophysique et médecine nucléaire
Faculté de médecine Simone Veil
Université Paris Saclay / UVSQ
INSERM UA8 « Radiations: Défense, Santé, Environnement »
pr.michel.bourguignon@gmail.com

BHPA - ABR - La Louvière 7 February 2020

We are not equal vis-à-vis IR: an old idea, a forgotten evidence, an economic and societal issue

- December 1895 : Roentgen discovers X rays
- February 1896: Becquerel discovers radioactivity
- 1896 : first radiotherapy by Victor Despeignes
- 1901 : first description by Pierre Curie of deleterious cutaneous effects of radium rays
- 1902 : first description by Frieben of radio-induced cancer
- 1911 : first description by Léon Bouchacourt of a difference of sensitivity to X rays, i.e., skin response after high dose IR

1911: First publication about individual radiosensitivity

To be peeled by... X-rays...

Chef du Service de Radiologie de l'Hôpital Dubois.

QUE DOIT-ON PENSER DU TRAITEMENT RADIOTHÉRAPIQUE DE L'HYPERTRICHOSE ET DE L'HYPERHIDROSE?

Dr. Léon Bouchacourt (1865-1949)

..." About the differences in sensitivity to Roentgen rays for different individuals, and for a given individual, for different body locations"...

radiosensitivity = tissue reactions

Reviews on individual response to ionizing radiation (1)

Creation of ICRP TG111: (Nov 2018) – Factors Governing the Individual Response of Humans to Ionizing Radiation

A fruitful clinical approach

Three types of patients/situations

- Patients with radiation-induced adverse tissue events attributable to cell deaths and loss of clonogenicity, i.e., complications and undesirable side effects of radiotherapy (with no error in dose delivery) which affect the quality of life and are not cancer effects = radiosensitivity
- Patients with cancer proneness and especially after exposures to ionizing radiation,
 linked to survival of DNA transformed cells and genomic instability = radiosusceptibility
- Patients with late tissue degeneration after exposures to ionizing radiation, e.g.,
 cataracts or cardiovascular effects, linked to cell and tissue ageing = radiodegeneration

Semantic clarification

- Radiosensitive persons are also radiosusceptible but one can be radiosusceptible (and cancer prone) without being radiosensitive (e.g., Li Fraumeni p53)
- Children are more radiosensitive than adults! When do they stop?
- Women are more radiosensitive means that they are more cancer prone, i.e., radiosusceptible

- Foray N, Bourguignon M and Hamada N. Individual response to ionizing radiation. Mutation Research 770 (2016): 369–386

A public health issue

Up to 20% of the population is concerned

- But a continuum between normal and highly pathological response
- Large population exposed to low doses ionizing radiation: medical (repeated exposures), radon, cosmic (planes), dismantling, nuclear accidents...
- The risks are higher than in normal population (e.g., family risk of breast cancer with no identified gene) but not taken into account by ICRP

Medical exposures are the most important of all exposures and steadily increase = <u>focus on patients</u>

- Radiotherapy of 50% of cancers with 80% cure but 8 % of radio-induced cancers
- Diagnostic CT and interventional radiology (58% of medical doses)

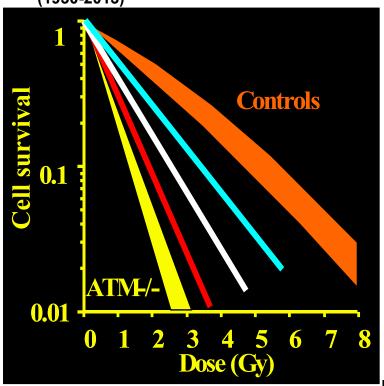

<u>Combined risks</u> of exposures to low doses of genotoxic compounds (chemicals...) = exposome with potentially supra-additive effects

1981: First correlations with individual radiosensitivity

Human clinical radiosensitivity = in vitro surviving fraction at 2 Gy

- Survival curves never cross: intrinsic radiosensitivity
 - There is a continuum in radiation responses
 - Quantitative correlation between survival fraction at 2 Gy (SF2) and local tumor control

Fertil and Malaise, Int J Radiat Biol Oncol Phys, 1981, 7(5):621-9 Deschavanne and Fertil, Int J Radiat Biol Oncol Phys, 1996, 34(1):251-66

The genetic syndromes associated with radiosensitivity: an obvious link to DNA DSB repair (70%)

but there are exceptions (30%)

Foray N, Bourguignon M and Hamada N. Individual response to ionizing radiation. Mutation Research 770 (2016): 369–386

- 27 syndromes with a genetic trait in this list
- All together > 5% of the population (ATM+/- = 1.5 %)
- Many other patients without known genetic trait exhibit clinical radiosensitivity
- Up to 20% of the population ?

Existing cohorts and biobanks suitable for radiosensitivity research

Dedicated radiosensitivity cohorts composed of patients referred to radiation biology studies for clinical radiosensitivity

- COPERNIC (France)
- RILA (France + various countries)
- RTOG/EORTC trials (various countries)

Other oncology cohorts

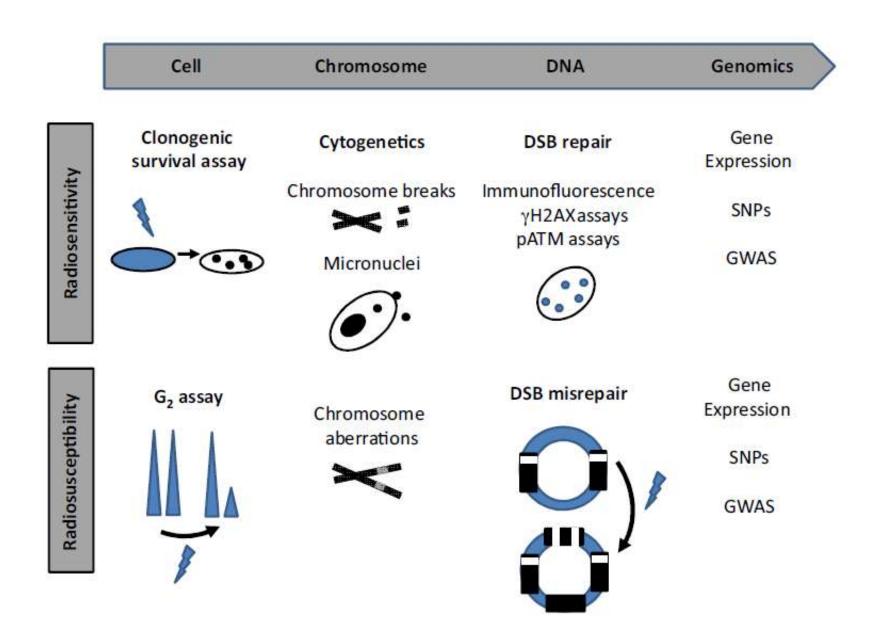

REQUITE (EU)

Other cohorts and biobanks

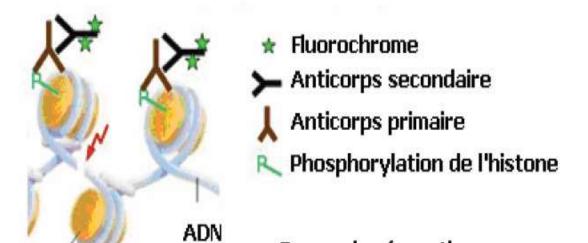

- Biobank of Eastern Finland
- CONSTANCES (France)
- EPIC (IARC)
- NAKO (Germany)
- UK Biobank

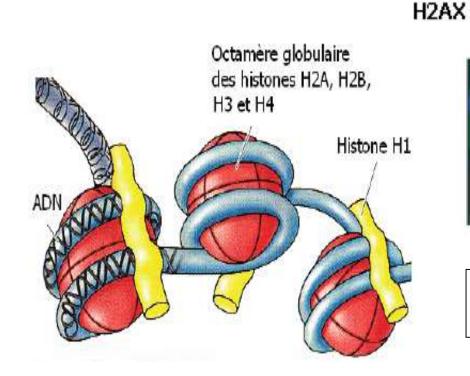

Major assays for evaluation of radiosensitivity and radiosusceptibility (not suitable for screening in routine clinical practice)

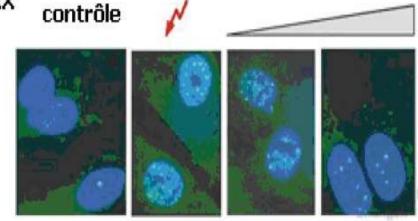

Immunofluorescence: a powerful technique of investigation

Temps de réparation

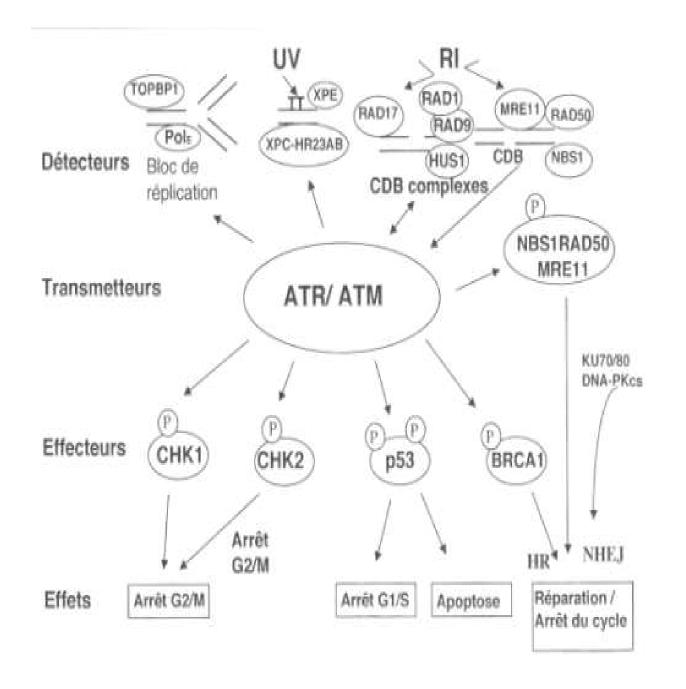

Blue coloration of chromatin with DAPI

Visualisation of radioinduced damages with immunofluorescent γH2AX foci

Immunofluorescence: a powerful technique of investigation

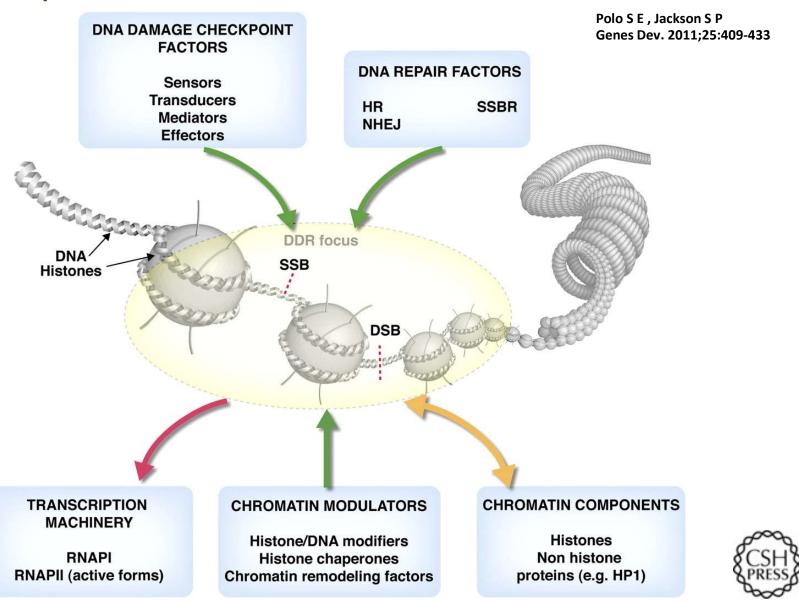

- Identification and quantification of DNA DSBs at the dose de 1 mGy by immunofluorescence anti-histones γ H2-AX (Rothkamm & Löbrich 2003) :
 - gain in sensitivity of 100 : threshold of 1 mGy
 - The effects of one single radiologic examination (e.g., one mammography) can be visualized and quantified
- Identification of poorly repaired DNA DSBs by immunofluorescence MRE11
- Other markers of signalization and repair pathways of DNA lesions (ATM, 53BP1, ...) can be studied by immunofluorescence

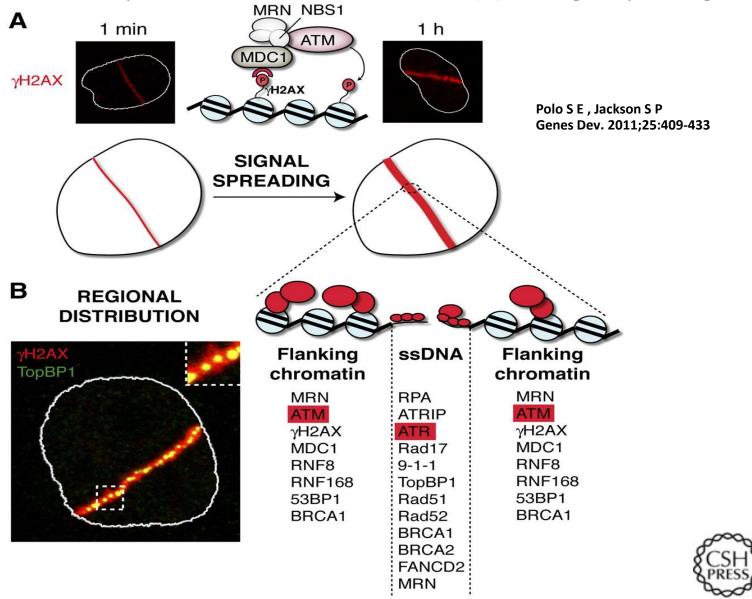

Cascade of signalization after DNA damage

So many potential targets to visualize by immuno fluorescence

Protein dynamics to and from sites of DNA breaks.

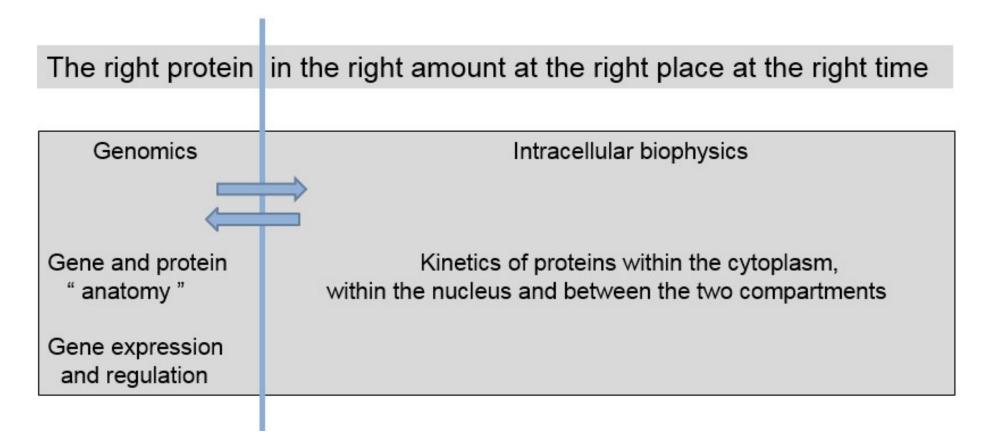

Spatial organization of DDR protein accumulation at DNA DSBs. (A) DDR signal spreading.

New approach with immunofluorescence: assessment of protein kinetics inside the cells, e.g., ATM translocation from cytoplasm to nucleus

Current assays for radiosensitivity

 pATM nuclear assay (ELISA on lymphocytes for screening + extensive evaluation on skin fibroblasts)

GROUP II

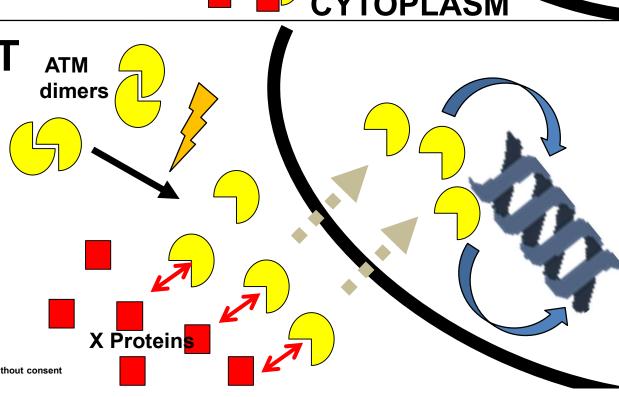

Delayed nucleo-shuttling of ATM Incomplete DSB recognition Incomplete DSB repair Moderate radiosensitivity High cancer risk

STATIN EFFECT

Acceleration of nucleo-shuttling of ATM Radioprotection

Bodgi et al. J Theor Biol 2013 Ferlazzo et al. Mol Neurobiol 2014 Granzotto et al., submitted

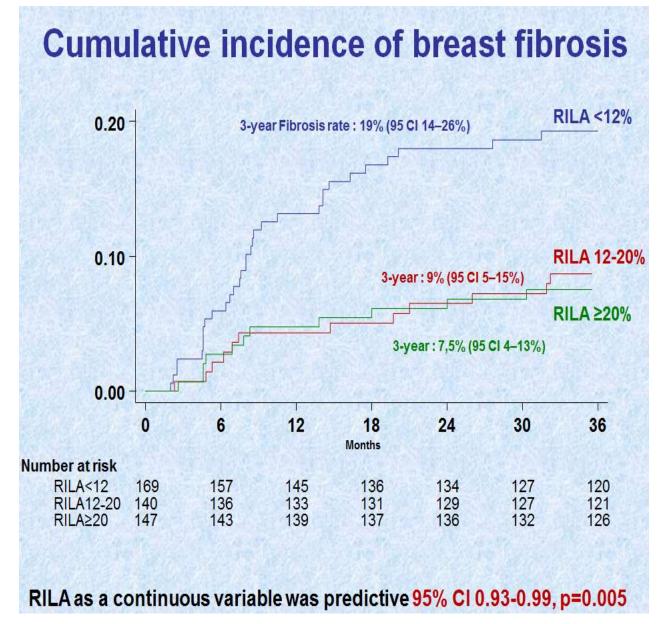

Radio-induced apoptosis of CD8 T-lymphocytes

RILA test

- Lymphocytes irradiated at 8 Gy
- <u>Inverse correlation</u>: The smaller the rate of apoptosis, the greater the radiosensitivity
- Test <u>predictive of late</u>
 complications only after
 radiotherapy, e.g.,
 breast fibrosis

 ≥ grade 2
 for a level of apoptotic
 lymphocytes <12 %

Azria et al, eBioMedecine 2015

CDKN1A as a marker of severe early radiation toxicity

Badie et al 2008, Br. J. Cancer 98: 1845-51 But also see Finnon et al 2012, Radiother Oncol. 105: 329-36

Radiosensitive patients may be radiosusceptible to cancer

- About 8% of patients treated for cancer by radiotherapy exhibit a second cancer in the field of exposure: secondary cancer or second primary cancer?
- These patients may be radiosusceptible, i.e., cancer prone with a particular susceptibility to IR, related to the survival of altered cells

Cosset JM, Hetnal M, Chargari C. Second cancers after radiotherapy: update and recommendations Radioprotection 2018, 53:101-105

Individual response at low doses IR

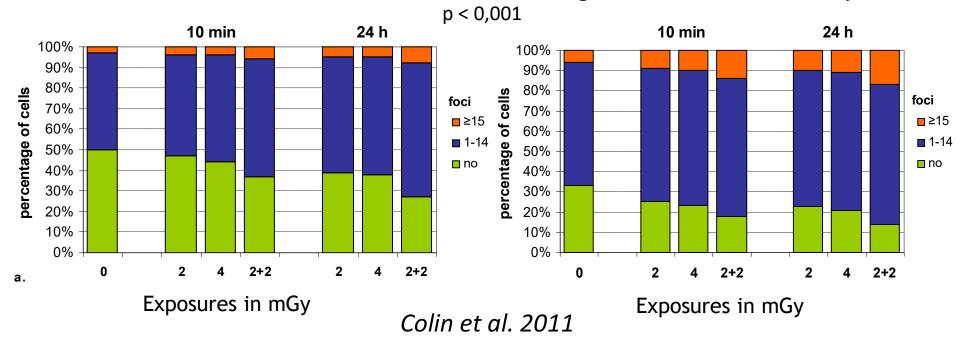

γH2AX foci quantified with human mammary epithelial cells exposed ex vivo in mammographic condition

Dose effect, repetition of dose effect, effect of induction of DNA DSBs between 10 min and 24h

The 3 effects increased

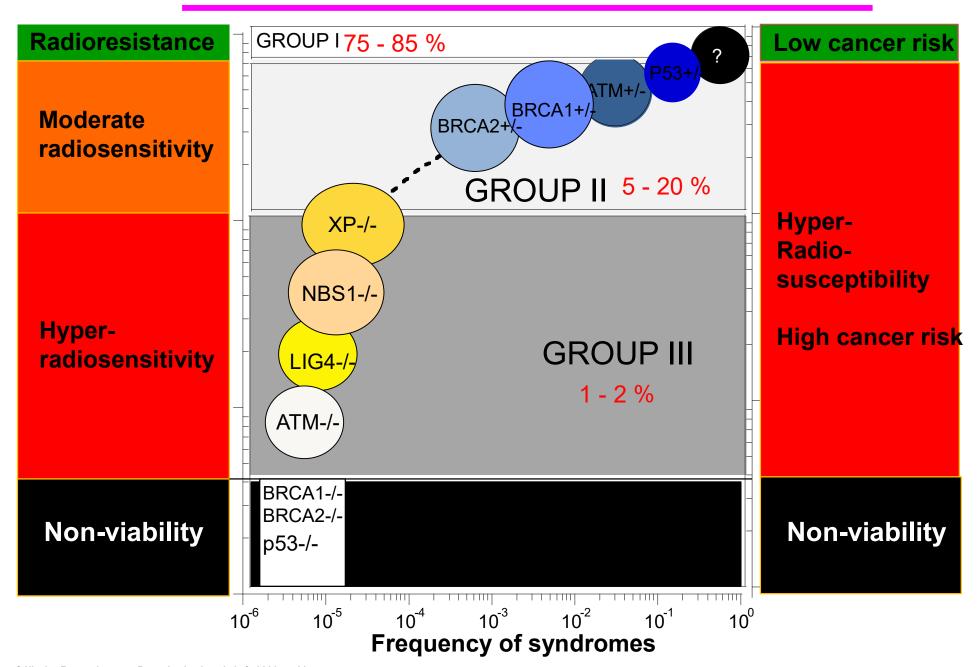

Low breast cancer risk

High breast cancer family risk

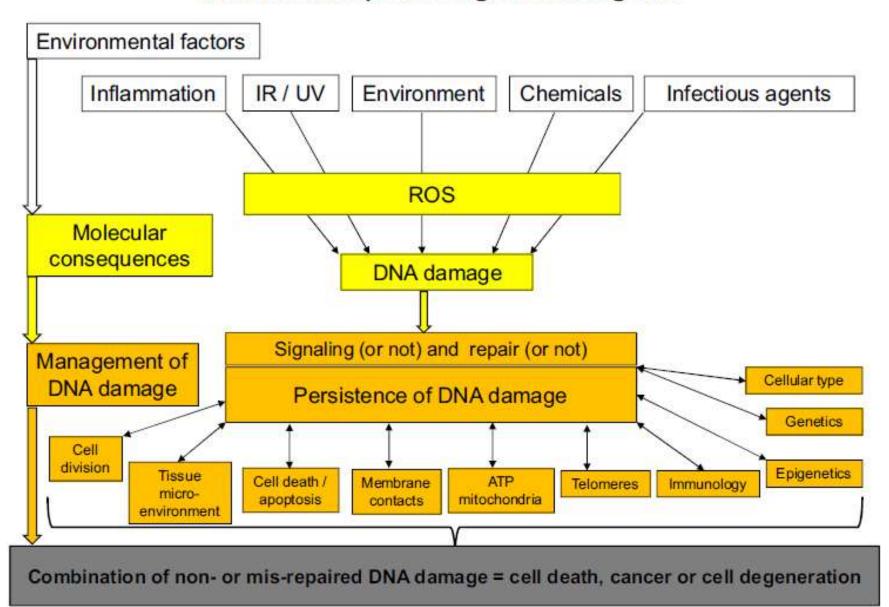

Radiosensitivity and radiosusceptibility

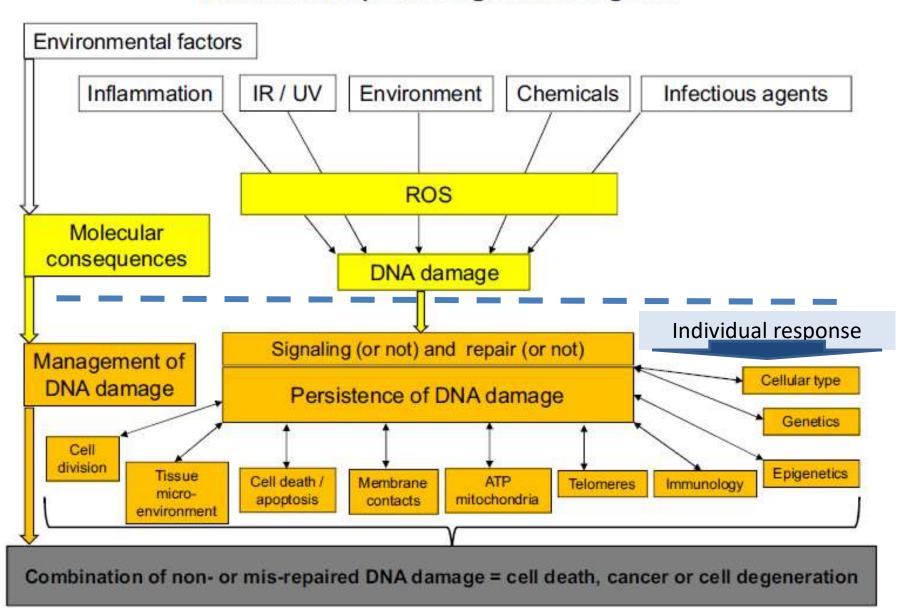

CANCER

Individual response to genotoxic agents

Individual response to genotoxic agents

Conclusion (1)

A new vision for radiological protection

<u>Identification of patients at risk</u> to control/decrease exposures to IR: personalized medicine and risk evaluation (ICRP TG111)

- Radiosensitive patients, to prevent or minimize the severe radio induced lesions (with alteration of quality of life) after radiotherapy, especially in children
- Radiosusceptible individuals, to anticipate cancer (prevention, screening...), notably in high family risk of cancer with no identified genes (majority of cases for breast cancer), in children, in persons exposed to radon ...
- Individuals at risk of radiodegeneration to prevent the disease or slow down the evolution

Conclusion (2) Still a long way to go?

In practice

- A few screening tests are already available for routine use in clinical practice
- Cross comparisons of tests are necessary on different cohorts for completing their validation
- Qualified and certified radiation biologists are necessary
- Results to be transferred to clinicians (radiation therapists...) for further decision and application

In research

- Further develop screening tests : protein kinetics / omic tools
- Design and use drugs to restore ATM translocation in neuro degenerative disease
- Understand the mechanisms of oncogenesis/degeneration (useful for cancer treatment?)
- Enlarge the vision to all genotoxic compounds at low doses

Thank you for your attention
